

Using the Sun in Buildings

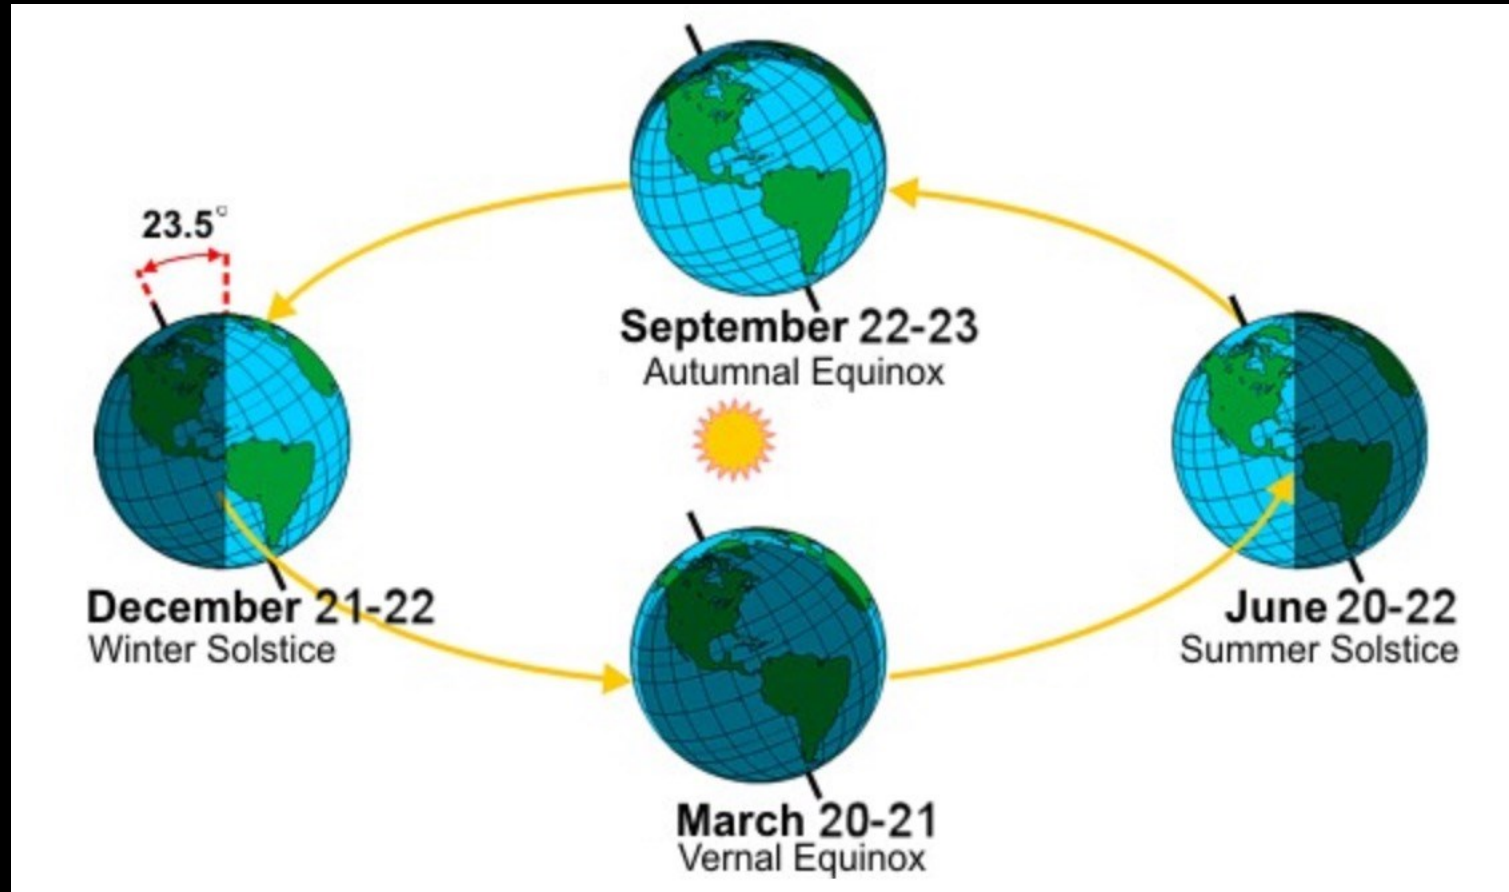

Twenty-Seventh Westford Symposium on Building Science

Why Bother?

Make better buildings, for people and the planet

- Use to provide space heating
- Avoid cooling load
- Heat domestic water
- Heat outdoor pools
- Make electricity
- Light buildings

The Earth's Axis is Tilted

Sun Paths

Solar Spectrum

| 366-Clear | 0.272 | 0.645 |

Calculating Solar Radiation (Insolation)

- Clear Day vs. Average Day
 - Most modeling software uses average day solar data, in order to calculate average annual solar performance (space conditioning, water heating, electricity, daylighting)
 - Clear day data is useful to calculate design cooling loads
 - Clear day data is also used to calculate amounts of energy storage, both thermal and electrical, and to size blowers and pumps for transporting solar energy

Fan-forced Solar Greenhouse

Active storage; passive release

- A blower moves air carrying excess solar heat from the greenhouse to water storage in the Thermomass basement below

Fan-forced Solar Greenhouse

- Peak *hourly* clear day insolation sizes the blower
- Peak *hourly* clear day insolation sizes the heat transfer from the air to the water containers
- *Daily* clear day insolation sizes the heat storage (300 five gallon water containers)

Modeling the Manifold Air Jets

Solar Radiation Calculators Online

<https://pvwatts.nrel.gov/>

The screenshot shows the PVWatts Calculator website. At the top, the header includes the 'PVWatts® Calculator' logo on the left and the 'NREL NATIONAL RENEWABLE ENERGY LABORATORY' logo on the right. Below the header, there is a 'Get Started:' section with a text input field containing '02575' and a 'GO »' button. To the right of this are links for 'English', 'Español', and 'Українська', along with 'HELP' and 'FEEDBACK' buttons. The main content area features a large image of solar panels. On the left of this image is an orange cross-shaped icon made of smaller squares. To the right of the icon, the text reads 'NREL's PVWatts® Calculator' followed by a description: 'Estimates the energy production of grid-connected photovoltaic (PV) energy systems throughout the world. It allows homeowners, small building owners, installers and manufacturers to easily develop estimates of the performance of potential PV installations.' In the bottom right corner of the solar panel image, there is a button that says 'Follow @PVWatts'.

PVWatts is free online software designed to model solar electric system performance

SUSTAINABLE BY DESIGNSEATTLE, WASHINGTON

toolsconsultingaboutcontact

Design Tools

Sustainable By Design provides a suite of shareware design tools on sustainable energy topics:

SUN ANGLE TOOLS

SunAngle
the premiere tool for solar angle calculations

SunPosition
calculates a time series of basic solar angle data

WINDOW TOOLS

Overhang Analysis
visualization of the shade provided by a window overhang at a given time, plus a chart depicting annual performance

Overhang Recommendations
suggested climate-specific dimensions for equator-facing window overhangs

Light Penetration
visualization of the penetration of sunlight into a room

Louver Shading
visualization of louvered shading system performance for an entire year

Vertical Fin Shading
visualization of a vertical fin shading system performance for an entire year

Window Heat Gain
calculation of monthly heat gain through windows

OTHER TOOLS

Panel Shading
visualization of the shading of rows of flat panel collectors throughout the year

USA Climate Data
monthly climate data for about 250 U.S. cities

We are sunlight, manifest as mind.

Effects of Tilt and Azimuth

Average Monthly kWh/m²/day by Azimuth and Tilt, Martha's Vineyard

Matching the Load to Tilt/Azimuth

- Is the load seasonal or annual?
 - Heating and pool heating are seasonal
 - Electricity and domestic water heating are annual
- Is occupancy seasonal?
 - Schools (and solar hot water seasonality)
- Is the system output exportable?
 - Only electricity is exportable (on a per building basis)

Effects of Location

Solar Radiation on a vertical surface facing South, kWh/m²/day

Matching the Aperture to Load

Distinguish between average and peak insolation

Matching the Aperture to Load

- January net heating load is 5,000,000 BTU
- Daily *average* January insolation = 953 BTU/sf
- Glazing SHGC = 0.60 (triple, 2 lites Cardinal 180)
- Glazing area to offset January heating load = **282 sf**
- Daily *clear day* January insolation = 1,733 BTU/sf
- Average January daytime heating load is 44,000 BTU
- Clear day solar gain is 293,000 BTU, so the net energy that needs to be stored is 249,000 BTU – this is a lot!
Interior temperature would rise ~34F. *Utilizability*
- Actual glazing area of **110 sf** is still somewhat oversized ☺ - old guideline of 8% south glass / floor area is too high for very low load buildings

Window Overhangs

Overhang Objectives

Heating season – don't block direct sun

Cooling season – block direct sun

The tricky part - the sun's path April 21st and August 21st is the same, but the heating/cooling load is not.

As the azimuth diverges from true south, overhangs become less effective. Overhangs on the east and west must be quite deep to shade the windows from low angle sun – these are known as porches (not Porsches)

Overhang Terminology

D - Overhang Depth

X - Separation Distance

H - Window Height

These dimensions can be in any unit of length, as long as they are the same - try furlongs

susdesign.com Overhang Analysis

<https://www.susdesign.com/overhang/index.php>

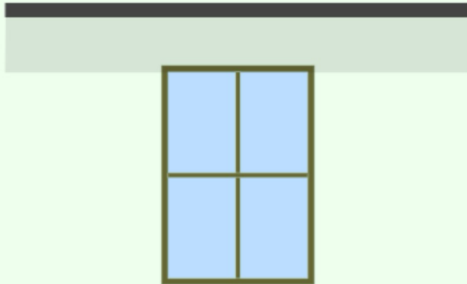

Overhang Analysis

This tool provides visual feedback about the performance of a horizontal window overhang. Please read the [introduction](#) before using this tool.

NOTE: This is a new overhang analysis tool, providing visual feedback of the overhang shade at the selected date & time, as well as an annual performance chart. This tool may not work in certain old browsers, so in that case you may wish to try a different browser, or use the [old version](#). Feedback is welcome on this new tool, and improvements continue to be made. [\[hide tip\]](#)

susdesign.com Overhang Analysis

Solar Pool Heating

- Pool collectors are typically unglazed low temperature plastic absorbers
- In the Northeast, collector aperture is 50-100% of the pool surface
- The most important conservation measure is a pool cover to suppress evaporation
- My *opinion* is that solar electric panels combined with a heat pump pool heater (HPPH) is a better investment because:
 - Excess energy can be exported
 - HPPHs use much less energy than propane pool heaters

Solar Pool Heating

Daylighting

Daylighting is the controlled admission of natural light from the sun and the sky to provide building occupants with the lighting needed to perform desired tasks.

Daylighting may save energy

Daylighting has multiple beneficial effects on human health

Masterfully done, daylighting can inspire and uplift.

MIT Chapel Eero Saarinen 1954

MIT Chapel Interior

Saving Energy with Daylighting

- To save energy, electric lighting needs to be controlled and turned down or off as daylighting provides light
- Today's tech allows electric lights to be continuously dimmed (vs step control) and it can be done by individual fixture
- Proper analysis of savings from daylighting must include energy used for heating and cooling

Lighting Efficiency

- Efficiency is units of light output per unit of energy input – it is measured in lumen/watt (lpw)
- One footcandle is one lumen/ft²
- What has changed over my working life is the efficiency of electric lighting – LEDs are available with lpw ratings of over 100
- LEDs can provide light with less cooling load than sunlight!

So – daylighting is optimally done with the amount of glazing needed for other purposes

Lighting and Perception

Good lighting facilitates our attention on that which within our field of vision is important –

- * to perform our intended tasks
- * to satisfy our innate biological needs
 - orientation in space and time
 - safety and security

We are confronted with innumerable stimuli and what we see informs our perception. Perception involves the brain processing what is seen and determining what is important vs. what is noise

“Perception thus differs from sensation by the consciousness of farther facts associated with the object of the sensation”
William James

Perception and Lighting

Basic Daylighting Principles

- Avoid glare
- Provide light from more than one direction
- Avoid beam sunlight on the work plane
- Minimize contrast between objects
- Use light, reflective surfaces to bounce light into the space
- Provide views to outdoors
- Give occupants control over daylighting sources

Glare (Not Daylighting)

Reducing Contrast

White surfaces adjacent to glazing

Reflective Surfaces

Daylighting and Climate

- Different climates – heating vs. cooling dominated; sunny vs. overcast – engender different daylighting strategies
- Sunny, hot climates exclude direct sun
- Cool, cloudy climates rely on the whole sky dome rather than direct sunlight
- Northern European architects specialized in daylighting in overcast conditions – Alvar Aalto, Eero Saarinen
- William Lam pioneered the integration of daylighting in both overcast and sunny conditions

Sidelighting

- Sidelighting (windows) is strongly dependent on orientation – north and south are optimal
- Windows need control of direct sun while maintaining access to the overcast sky
- Sidelighting typically can provide daylight penetration into the space roughly 1-1/2 times the glazing head height

Sidelighting Control

- Control of sunlight can be fixed or operable, internal or external
- Operability can be manual or automated
- Fixed sun control elements optimally should not suppress lighting in overcast conditions in climates with significant overcast conditions

Perforated Shades

TS – Total Solar Transmittance
 RS – Solar Reflectance
 AS – Solar Absorptance
 TV – Visible Light Transmittance

⊖ 1550 • 3% Open • Solar Optical Properties

| > SOP DEFINITIONS: | TS | RS | AS | TV |
|--------------------|----|----|----|----|
| 1551 White | 21 | 65 | 15 | 17 |
| 1569 Silver Birch | 12 | 50 | 38 | 18 |
| 1566 Eggshell | 12 | 58 | 31 | 8 |
| 1552 Beige | 8 | 49 | 43 | 4 |
| 1563 Grey | 4 | 25 | 71 | 3 |
| 1570 Shadow Grey | 4 | 9 | 87 | 4 |
| 1554 Black/Brown | 3 | 5 | 92 | 3 |

External Operable Blinds

- To be effective, blinds need a width/spacing ratio of 2 or more
- Exterior blinds are more effective at keeping sun out
- Blinds can be reflective on top to re-direct sunlight to the interior ceiling

Internal Operable Reflective Blinds

People can see out,
and direct sunlight is
directed to the ceiling
plane

Light Shelves

- External LS can bounce more direct beam into the room, and shade the lower window
- But...it shades the lower window from diffuse light on overcast days
- Internal LS
 - Evens light levels front to back of the room
 - On S facade, prevents direct beam on workplane or in occupants' view
 - Lowers total light admitted

Glazing with Light Shelves

- The upper glazing needs no shading devices
- As the orientation shifts from south the length of the LS must increase
- The glazing below the LS receives shades, manually controlled by the occupant
- This approach allows daylight penetration even in direct sun

Glazing with Light Shelves

Toplighting

- Toplighting can be skylights or south/north facing roof monitors
- Skylights may bring in more cooling load but...
- South-facing roof monitors may shift peak cooling load to the heating season, and need more glazing
- Skylights are very effective in overcast conditions
- In sunny conditions, skylights with clear glazing need to be placed to avoid direct beam sunlight on the work plane, but they can be used to provide some “sparkle” to spaces
- Translucent glazing in direct sun is still extremely bright and can cause glare issues

Toplighting

Excessively daylighting lobbies and circulation spaces will make spaces where people work seem darker so they will turn the lights on

Toplighting

Skylighting

Skylighting

Daylight Factor

Daylight Factor (DF) is the ratio of light on a horizontal plane outdoors to light on the work plane indoors

$$DF = SFR \times VLT \times WF \times CU$$

SFR – Skylight area to floor area ratio

VLT – Visible Light Transmittance

WF - Well Factor

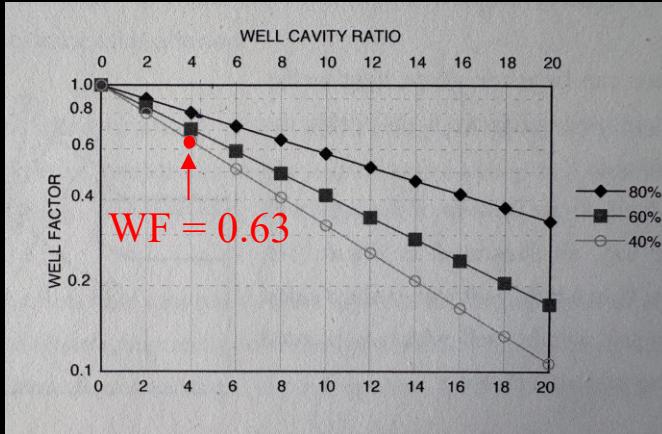

CU– Room Coefficient of Utilization

Well Factor - how effective the skylight well is at transmitting the light that the skylight admits into the space
Well Factor depends on the geometry of the well, expressed by the *Well Cavity Ratio*, and the reflectance of the well enclosure

Daylight Factor

$$\text{Well Cavity Ratio} = 5 \times H \times (W+L) / (W \times L)$$

Well Factor vs WCR
and reflectance

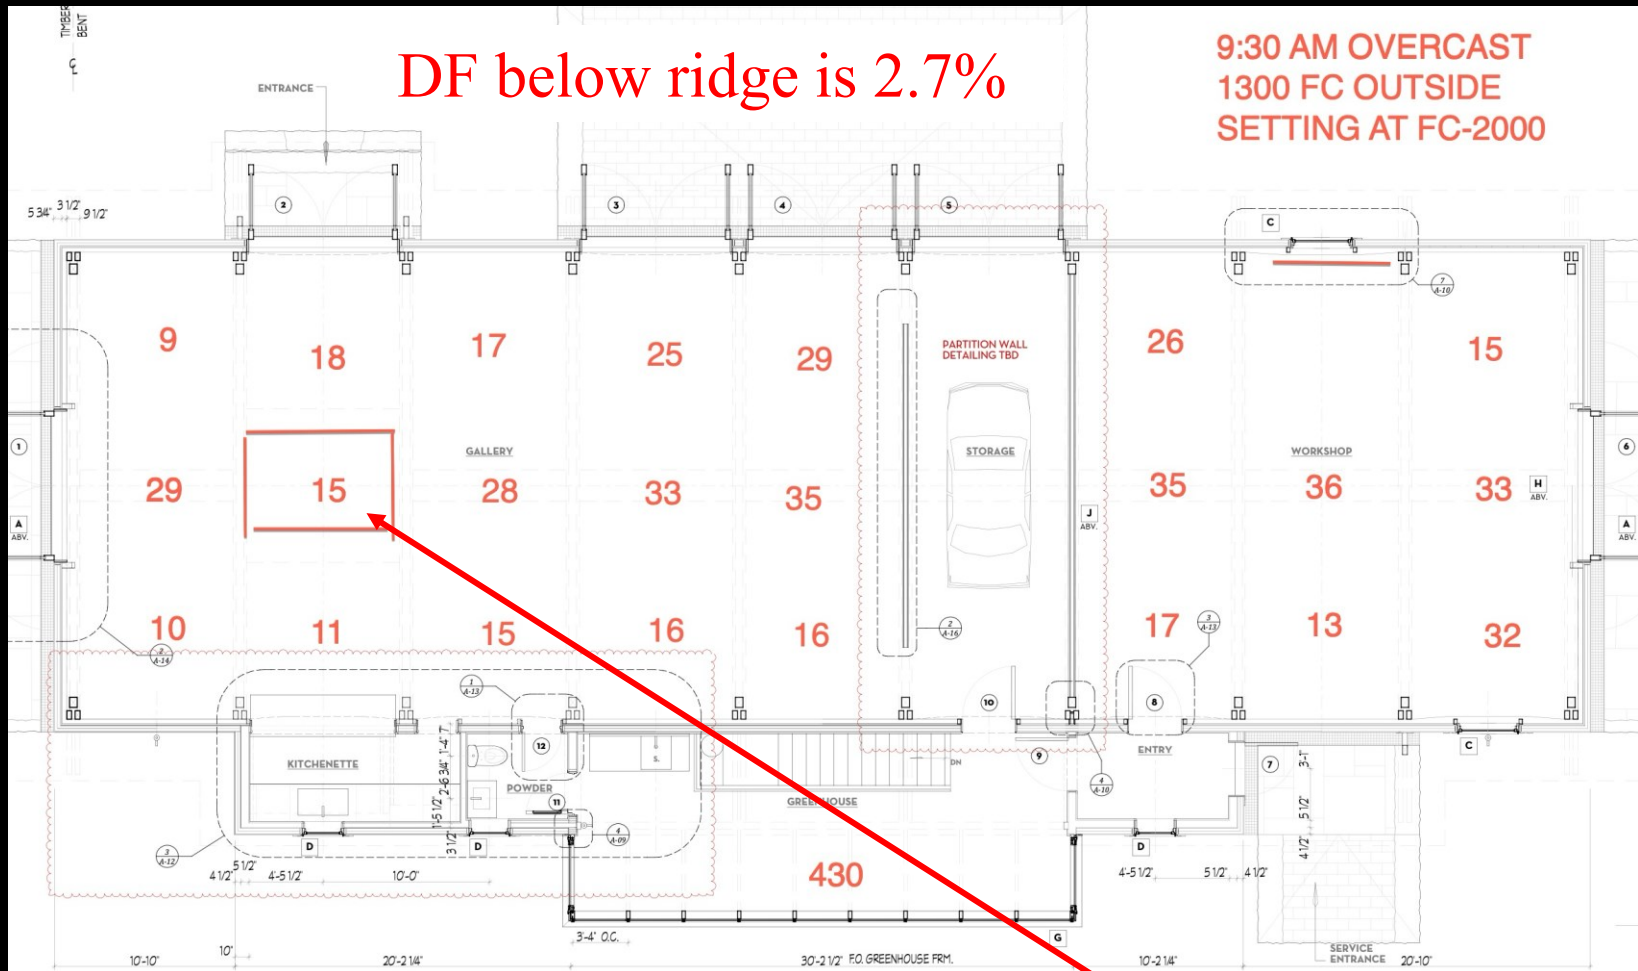

Daylight Factor for ridge skylight

$$DF = SFR \times VLT \times WF$$

$$= 0.07 \times 0.56 \times 0.63$$

$$= 2.6\%$$

Daylight Factor Results

Light levels are lower beneath the cupola

Skylighting

Light manipulated at the roof
